ACCESS STATEMENT

These digitized collections are accessible for purposes of education and research. We have indicated what we know about copyright and rights of privacy, publicity, or trademark. Due to the nature of archival collections, we are not always able to identify this information. We are eager to hear from any rights owners, so that we may obtain accurate information. Upon request, we will remove material from public view while we address a rights issue.

CONSTRAINTS STATEMENT

The Arizona Geological Survey does not claim to control all rights for all materials in its collection. These rights include, but are not limited to: copyright, privacy rights, and cultural protection rights. The User hereby assumes all responsibility for obtaining any rights to use the material in excess of "fair use."

The Survey makes no intellectual property claims to the products created by individual authors in the manuscript collections, except when the author deeded those rights to the Survey or when those authors were employed by the State of Arizona and created intellectual products as a function of their official duties. The Survey does maintain property rights to the physical and digital representations of the works.

QUALITY STATEMENT

The Arizona Geological Survey is not responsible for the accuracy of the records, information, or opinions that may be contained in the files. The Survey collects, catalogs, and archives data on mineral properties regardless of its views of the veracity or accuracy of those data.

Engineering/Geology

Office

January 18, 1963

Date

Schwarz-Guzman lease

SUBJECT: Copper prospect south of
Florence, Pinal County, Arizona

TO: D. M. Kentro

General

On January 9, 1963, we visited leased claims held by Messrs. W. M. Schwarz and M. Guzman, P. O. Box 1145, Miami, Arizona. The claims are located in the Picacho Mining District south of Florence in T. 7 S., R. 10 E., and comprise all of sections 7, 8, and 17; and part of sections 3, 4, 5, 6, 9, 18, and 20.

The claims, owned by Mr. Randall and three others, have been grouped together for a total of 194 unpatented lode type contiguous claims on federal land. Mr. Schwarz presently holds a 5 year lease with an option to buy.

Sample Data

Six samples were taken during the examination. The assay results are tabulated below:

Sample No.	Width	Au	Ag	Cu	SiO ₂
# 5158 cut	33.0'	tr	nil	0.24	86.5
# 5159 cut	15.0'	tr	nil	0.06	71.1
# 5160 cut	50.0'	tr	nil	0.09	58.8
# 5161 grab around shaft collar		tr	nil	0.88	
# 5162 cut	10.0'	0.01	0.2	0.45	
# 5163 grab along 60.0' of length		tr	nil	0.36	

Although the assay results are low, outcrops showing copper are distributed over several square miles suggesting a porphyry type deposit may be found in this area. The best assay, # 5161, (see sketch) is about midway between the North Star (Randall Group--area recently mapped by a major mining company) and surface cut #'s 5158-59-60.

Geology

In the outcrops examined chrysocolla is the main copper mineral--locally scattered blebs of chalcocite are present. Oxidized copper minerals were noted in quartz monzonite-monzonite porphyry, andesite dikes, granites, quartzites, and argillaceous sediments. Volcanics in the area range in composition from rhyolite to felsite. These rocks, on the Pinal County Geologic Map, are lumped together as preCambrian granites. It is very likely some of the igneous rocks have intruded Paleozoic sediments and are therefore younger than preCambrian--perhaps Cretaceous in age. This possibility further enhances the chances of a porphyry type copper deposit--preCambrian age porphyry deposits are rare to unknown.

Mining

Copper has been mined on these claims from surface cuts and shipped to the Magna Smelter for flux--the shippers apparently had free smelting for the high silica content. Samples # 5158-59-60 were taken from one of these cuts (see sketch). Some mining is still active on the North Star Group about 1.5 miles southwest of samples # 5158-59-60.

The general surface area is very similar to a deposit of copper situated some 20 miles to the southeast which consists of 17 claims and was worked by Messrs. Schwarz and Gusman several years ago and which appear to have the same general northwest trend.

Diamond Drilling

On the southern part of this property at least 6 diamond drill holes have been put down (see sketch). The logs from this drilling are not complete but indicate a grade of 0.35 to 0.50 % copper over the entire length of the holes. The holes ranged in depth from 125 to 800 feet. Much of the area is covered with alluvium--some of the drill holes show 300 feet of gravel overburden.

Conclusions

The area around the North Star (about 1 sq. mi.), in the Randall Group, has been recently mapped by the exploration division of a major mining company. Apparently this company is still interested in the property.

The numerous copper stained outcrops scattered over the Schwarz-Gusman lease define a very large area of mineralization. It is recommended this area be mapped on aerial photographs with a view to further investigation in the future, if warranted, by geophysics or diamond drilling.

RANDALL COPPER PROPERTIES

PICACHO DISTRICT--PINAL COUNTY--Arizona.

RANDALL COPPER PROPERTIES

The mining properties in this report are situated, in so far as could be ascertained, in the Picacho Mining District, in sections 6 and 7, T. 7 S. R. 10 E., Gila Salt River Meridian in Pinal County, State of Arizona. Florence is the county seat of Pinal County.

The properties are about 25 miles southwest of Florence on Highway 80. Of that distance, 20 miles are paved and five miles are dirt road from the turn off west from Highway 80.

Coolidge, the nearest town, is distant 20 miles by a partly paved and dirt road. An old dirt road, formerly used, until washed out by floods, is distant 10 miles from Coolidge. A few days with a dozer outfit could make it passable again.

The holdings comprise 82 lode claims, held by possessory rights. Five claims are located under the name of North Star Nos. 1 to 5, inclusive; the rest, under the name Cora Nos. 1 to 77, inclusive. Some of the latter claims cover the relative flat plateau area adjacent and are overlaid by a bedding of caliche lime, the thickness as yet undetermined.

The area lies within an ancient inland sea bed, which by successive seismographic disturbances over eons of time, resulted in the depositions of one of the largest known zones of copper bearing ores in existence.

The geology can be interpreted from the surface outcrops and open cuts as a series of quartz-monzonite cross-fissures interposed in a porphyry-rhyolite intrusive; lenticular stratas of the older granitic rocks were noted as evidence of deep seated origin. The older formations were thrust through the upper stratas by successive seismic and subsident actions.

COPY.

At some period of movement, a narrow body of diabase was thrust through the formation. This intrusion bears a north-south strike, whereas the quartz-monzonite fissurings occur at variable angles of strike. The copper ore bearing rocks, in general, occur with few exceptions at the point of contact of the cross-fissures along the fracture planes of the quartz-monzonite and altered adjacent country rock in the line of fracture. As silica is the predominate constituent of the quartz-monzonite and monzonite-porphyry, the greater part of the ores occurs as various forms of copper silicates, of which chrysocolla is the most abundant. Some minute segments of chalcocite were noted, interposed in the lenticular stratas of silicious ores, which undoubtedly are of secondary origin. Minute particles of cuprous oxides and carbonates were noted. The presence of activated limestone being absent accounts for the low contents of the oxides and carbonates of copper.

This zone comprises an area extending westerly to the Picacho uplift, and easterly to the more extensively developed and better known areas as Superior, Miami, Globe, Ray and others within the rim of the basin.

Due to the pronounced surface exposures of the mineralized zones on the easterly horizons of these areas, the earlier prospectors and mining men gave their time and endeavors to these locales, at the neglect of some of the westerly horizons where little or no evidence of outcrops or exposures were evident.

With the present world price of copper, more attention is now being directed to the westerly horizon of the basin; and the properties under consideration comprise a part of this zone.

In my observations of the surface one point stood out clearly: the similarity of the area to the Coronado ore body at Metcalf, Arizona, which I quote:

COPY.

"The Coronado ore body or vein strikes east to northeast and has thrown quartzite against a Pre-Cambrian granite; it is a cementation of breccia on the Coronado fault. The ore body occurs as a quartzite against a Pre-Cambrian granite. A diabase dyke intruded into this fault before movement had ceased.

"The primary mineralization was similar to that of the fissures in the monzonite porphyry, but alterations resulted in the formation of a zone of oxidized ores, and one of secondary sulphides.

"This is in contrast with the deposits in limestone, which were mostly oxidized ores, and those in the monzonite porphyry were mostly sulphide ores. A further contrast was noted in that the reactivated limestone yielded oxidized ores, and the relatively inert monzonite porphyry yielded secondary chalcocite, whereas the intermediate rocks of the Coronado yielded both."

Excerpts from the Arizona Bureau of Mines, University of Arizona. The author was liaison officer and assistant to the George Millar, Superintendent and Mining Engineer of the Coronado Mine, Metcalf Division of Arizona Copper Co., Clifton Arizona, during World War I, 1917-18. Remarks which I quote from information given to me while stationed at Metcalf, Arizona.

During the early years of copper mining in the southwest territories, little attention was given to ground which failed to indicate copper bearing ores on the surface.

The Coronado vein was one of the many other similar cases in the course of events of that period.

Not until the old Arizona Copper Co. of Morenci, Arizona, a British corporation, erected their smelter at Clifton, Arizona, and surface operations were intensified for a larger source of silicious ore required for their smelter operations, was the Coronado vein discovered as it is known today.

The discovery was the result of driving the 7th level northerly to the north portal of said level. In the course of this work, the tunnel cut one side of the vein. Further development resulted in the opening up of one of the largest bodies of silicious ore discovered at that period.

This proved to be a windfall, as the silicious ores needed contained copper and some values in gold and silver within a few miles of their smelter.

The Coronado vein information has been used as a comparative description due to the similarity of the surface croppings.

The present workings have been confined to a limited area, in comparison to the properties as a whole; most of the developments are centered on the North Star group of five claims and are still in the prospective stage. The greatest depth attained is a nearly vertical shaft approximately 45 ft. in depth, following a fracture filled zone of brecciated quartz-monzonite 4 ft. in width, with low copper contents. (This shaft, for clarification in this report, is referred to as the Randall shaft.)

A similar condition was noted in an old, abandoned shaft about 200 ft. southerly from the Randall Shaft. This shaft, which is reported to be 340 ft. deep, and has a water level at 40 ft., was abandoned in the long past and no definite information is available, except the usual bizarre stories connected with old workings. Nevertheless, if the depth corresponds to the statements made, it should be unwatered at a later date, for what information it might lend to the geological data of the area.

Several open cuts of various dimensions have been opened, exposing the formations for study, particularly the faultings and subsidences and cross faultings and subsequent mineralization as the result of the cross faultings. Apart from the aforesaid surface exploratory work, no work has been performed of any consequence to evaluate the properties below the surface faulted zone.

SUMMARY:

The mineralization zone covers a considerable area and warrants a systematic evaluation of the holdings by one of the various geophysics methods applicable to this type of deposition. If the geophysics findings are favorable, the area should be core-drilled in a grid pattern, as a result of the geophysics map readings, to determine the value of the deeper mineralized zones beyond the zone of the surface faulting.

The surface mineralization so far uncovered is indicative of having originated from a depth below the surface fault zone.

Under the present and future market for copper, a high price is assured for a considerable period of years. The properties have sufficient merit to recommend their development. Another factor in favor of the properties is that they are located in an area adjacent to several commercial copper smelting plants, or if the ores result favorably for leaching, the chemicals essential for a leaching plant are produced and available in the State of Arizona.

Apropos to a leaching plant, a sufficient water supply would be required for this type of operation -- an economic problem that has not been determined at this writing.

LOCATION

NORTH STAR MINE

PINAL COUNTY

RRB WR 8/29/80: Bonnie Mochizuki, P.O. Box 416, Cottonwood, Arizona 86326, was in to discuss the North Star Mine, south of Florence in Pinal County. She reports that there is no record of it in Florence or at the BLM. Says it is not patented and there is no record of assessment work or refileing.

RRB WR 10/17/80: Norman Adams, 883-8857, was in to look at the North Star and Little Hill Mines in Pinal County. He is considering a copper leaching operation at one or both of them.

RRB WR 2/15/85: Visited the North Star Mine, Sec 8, T7S R10E, Picacho Mtns. Pinal County. Russell Stewart, who is living on the property, reports that Pearce Trucking of Casa Grande is removing the overburden, running it through a crushing and screening plant and providing sand and gravel to the CAP can site. He didn't say what financial arrangements were made but seemed very pleased to get stripping done while the price of copper is so low.

NORTH STAR MINE

PINAL COUNTY

To North Star Mine (turnoff at mile post 117½ West) - watchman at mine - Randall on his placer claims near Black Canyon - no activity at mine camp. Watchman said some outfit from Tucson was going to examine the mine. FTJ WR 4-18-69

Calumet Silver Mining Corp. of Albuquerque has the North Star near Florence, another property at Tombstone. Also a property in the Chiricahua's. GWI Note 9-12-69

Went to the North Star Mine and met Frank Randall - the owner. He and three other men were getting out a carload of high grade oxidized copper ore to be sold at Hayden. This property was optioned about a month ago to Essex-International Wire Co. of Michigan, who has Heinrichs of Tucson doing the evaluation. Mr. Randall also has a property in Bloody Basin know as the Brooklyn where he has previously mined about 250 tons of Cu, Ag, Au ore and will go there soon to rebuild the road so the ore can be hauled out. He also has another oxide copper prospect on State land about 12 miles south of the North Star which he is trying to sell to Essex. GW WR 7-17-70

Frank Randall has quit working the North Star mine. So has Heinrichs. The watchman didn't know if Essex Wire & Cable Co. had dropped their option or not. Mr. Randall is now working his mine in Bloody Basin but is living at Bumble Bee. Randall shipped 30 tons of 10.5% Cu to the Magma smelter. Heinrichs drilled seven 150'-200' holes with a dry rotary rig. GW WR 10-26-70

Went on down to Frank Randall's North Star Mine. The watchman said Mr. Randall has contacted several companies with regard to mining his deposit of copper, but none have made a deal as yet. He also stated that Mr. Randall was doing considerable prospecting at the old Brooklyn Mine in Bloody Basin where 3 men are employed. GW WR 5-10-71

Went to the North Star mine of Frank Randall where the watchman said they were contemplating a small leaching operation but would first try to get some capital from a placer operation near Bumble Bee, where Mr. Randall now lives. GW WR 4/3/72

RRB WR 4/22/80: Discussed leaching of copper ores with Norman Adams, 708 South Jones, Mesa, Arizona 85204. He is considering buying or leasing the North Star Mine south of Florence, Pinal County, and setting up some type of leaching operation. He has been in the sand and gravel business but knows nothing of the metallurgy involved. He is also interested in finding a small sulfide copper property to operate.

RRB WR 4/25/80: Visited North Star property south of Florence (Pinal County). No one was there but a visitor who knows the caretakers--William Teigen 885-5917. He showed me around the property. There were several open cuts and some old shafts that showed copper mineralization. Principally chrysocolla and malachite in granite.

A heap leaching and "tin" can cementation operation had been tried on a small scale at some time in the past. The ore appears amenable to this type of operation if it is in sufficient quantity. Also stopped at an adit approximately a mile away that was run on a narrow vein containing considerable chrysocolla. It may be a part of this property.

PHOENIX 7, ARIZONA

Tucson, Arizona,
June 18, 1964

MEMORANDUM

To: Frank P. Knight, Director
From: Axel L. Johnson, Field Engineer
Subject: Exploration at the North Star Mine

Field engineer received the following information on June 12, 1964:

The North Star Mine area, 12 miles south of Florence (Sec. 6 - T 7 S - R 10 E) is now being diamond drilled by Magma Copper Co., with Joy Drilling Co. doing the drilling. (1 drill rig).

They are now reported to be drilling the 4 th hole, and the holes are reported to be about 1,000 ft. deep.

Oct. 1962 Active Mine List shows the North Star Mine was operated by Mike Guzman of Superior at that time. (See L. A. Smith for particulars).

DEPARTMENT OF MINERAL RESOURCES

STATE OF ARIZONA

FIELD ENGINEERS REPORT

Mine Northstar Mine

Date 9-20-62

District Owlhead Dist., Pinal Co.

Engineer Lewis A. Smith

Subject: Conference with Mike Guzman, at Superior, 9-20-62.

Mr. Guzman stated that Guzman and Schwartz were mining copper-silica ore at the Northstar and delivering it to Magma Copper Company's smelter. Mike said they were not making much on a carload a day. The ore runs about 85-87 percent silica with about 1.25 percent or less ~~silica~~ *in Copper*. The ore is, with the exception of local chalcocite veinlets or blebs, oxidized to chrysocolla and some malachite.

active 10-62 - 3 men working

DEPARTMENT OF MINERAL RESOURCES

STATE OF ARIZONA

FIELD ENGINEERS REPORT

Mine Northstar Mine Date June 25, 1962
District Owl Head District, Pinal Co. Engineer Lewis A. Smith
Subject: Interview with Mike Guzman, at Superior June 21, 1962.

Claims: About 100

Location: Approximately 16 miles South of Florence and thence 11 miles W.

Owner: Frank Randall, Coolidge

Operators: Guzmans and Schwartz, of Superior (partnership agreement with Randall).

Work & Only shallow pits and cuts. The present silica pit is in
Geology: schist and monzonite (?) intrusions containing veins and small masses of quartz. The quartz is dense, fine-grained, and impregnated by chrysocolla, malachite and some chalcocite altering to cuprite and copper oxidized minerals (mainly chrysocolla). The near surface silicified material runs 1-1½ percent copper and approximately 80-85 percent silica. Several 10-ton truck lots have been delivered to Magma Copper Company, at Superior. The haul is approximately 60 miles. Guzman said that the material, where being worked, had become better with depth and appeared to be widening a little. He stated, also, that unless the copper content can be increased, the operation is a little over marginal.

1/28/60

North Star Mine

Info. H.Clyde Davis

Location In Pinal Co., about 15 miles S. of Florence in the Picacho Range. Turn S. of Highway 80 at the 117 mile post.

Minerals Copper oxides & carbonates.

Past Operations Exploration work was conducted in 1958 & first part of 1959 by S. W. Mining Industries, 1000 N. Mountain Ave., Tucson -- H. Clyde Davis, Mgr. 2,000 ft. of drilling was done by Vought & Cloeter, Ltd., Tucson.

Present Operations

Frank Randall, Black Canyon Road, Phoenix is now sinking a 100 ft. shaft on the vein, acc. to Mr. Davis.

This property active Feb. 1959

North Star file

RANDALL COPPER PROPERTIES

PICACHO DISTRICT-- PINAL COUNTY--Arizona.

RANDALL COPPER PROPERTIES

The mining properties in this report are situated, in so far as could be ascertained, in the Picacho Mining District, in sections 6 and 7, T. 7 S. R. 10 E., Gila Salt River Meridian in Pinal County, State of Arizona. Florence is the county seat of Pinal County.

The properties are about 25 miles southwest of Florence on Highway 80. Of that distance, 20 miles are paved and five miles are dirt road from the turn off west from Highway 80.

Coolidge, the nearest town, is distant 20 miles by a partly paved and dirt road. An old dirt road, formerly used, until washed out by floods, is distant 10 miles from Coolidge. A few days with a dozer outfit could make it passable again.

The holdings comprise 82 lode claims, held by possessory rights. Five claims are located under the name of North Star Nos. 1 to 5, inclusive; the rest, under the name Cora Nos. 1 to 77, inclusive. Some of the latter claims cover the relative flat plateau area adjacent and are overlaid by a bedding of caliche lime, the thickness as yet undetermined.

The area lies within an ancient inland sea bed, which by successive seismographic disturbances over eons of time, resulted in the depositions of one of the largest known zones of copper bearing ores in existence.

The geology can be interpreted from the surface outcrops and open cuts as a series of quartz-monzonite cross-fissures interposed in a porphyry-rhyolite intrusive; lenticular stratas of the older granitic rocks were noted as evidence of deep seated origin. The older formations were thrust through the upper stratas by successive seismic and subsident actions.

COPY.

At some period of movement, a narrow body of diabase was thrust through the formation. This intrusion bears a north-south strike, whereas the quartz-monzonite fissurings occur at variable angles of strike. The copper ore bearing rocks, in general, occur with few exceptions at the point of contact of the cross-fissures along the fracture planes of the quartz-monzonite and altered adjacent country rock in the line of fracture. As silica is the predominate constituent of the quartz-monzonite and monzonite-porphyry, the greater part of the ores occurs as various forms of copper silicates, of which chrysocolla is the most abundant. Some minute segments of chalcocite were noted, interposed in the lenticular stratas of silicious ores, which undoubtedly are of secondary origin. Minute particles of cuprous oxides and carbonates were noted. The presence of activated limestone being absent accounts for the low contents of the oxides and carbonates of copper.

This zone comprises an area extending westerly to the Picacho uplift, and easterly to the more extensively developed and better known areas as Superior, Miami, Globe, Ray and others within the rim of the basin.

Due to the pronounced surface exposures of the mineralized zones on the easterly horizons of these areas, the earlier prospectors and mining men gave their time and endeavors to these locales, at the neglect of some of the westerly horizons where little or no evidence of outcrops or exposures were evident.

With the present world price of copper, more attention is now being directed to the westerly horizon of the basin; and the properties under consideration comprise a part of this zone.

In my observations of the surface one point stood out clearly: the similarity of the area to the Coronado ore body at Metcalf, Arizona, which I quote:

COPY.

"The Coronado ore body or vein strikes east to northeast and has thrown quartzite against a Pre-Cambrian granite; it is a cementation of breccia on the Coronado fault. The ore body occurs as a quartzite against a Pre-Cambrian granite. A diabase dyke intruded into this fault before movement had ceased.

"The primary mineralization was similar to that of the fissures in the monzonite porphyry, but alterations resulted in the formation of a zone of oxidized ores, and one of secondary sulphides.

"This is in contrast with the deposits in limestone, which were mostly oxidized ores, and those in the monzonite porphyry were mostly sulphide ores. A further contrast was noted in that the reactivated limestone yielded oxidized ores, and the relatively inert monzonite porphyry yielded secondary chalcocite, whereas the intermediate rocks of the Coronado yielded both."

Excerpts from the Arizona Bureau of Mines, University of Arizona. The author was liaison officer and assistant to the George Millar, Superintendent and Mining Engineer of the Coronado Mine, Metcalf Division of Arizona Copper Co., Clifton Arizona, during World War I, 1917-18. Remarks which I quote from information given to me while stationed at Metcalf, Arizona.

During the early years of copper mining in the southwest territories, little attention was given to ground which failed to indicate copper bearing ores on the surface.

The Coronado vein was one of the many other similar cases in the course of events of that period.

Not until the old Arizona Copper Co. of Morenci, Arizona, a British corporation, erected their smelter at Clifton, Arizona, and surface operations were intensified for a larger source of silicious ore required for their smelter operations, was the Coronado vein discovered as it is known today.

COPY.

The discovery was the result of driving the 7th level northerly to the north portal of said level. In the course of this work, the tunnel cut one side of the vein. Further development resulted in the opening up of one of the largest bodies of silicious ore discovered at that period.

This proved to be a windfall, as the silicious ores needed contained copper and some values in gold and silver within a few miles of their smelter.

The Coronado vein information has been used as a comparative description due to the similarity of the surface croppings.

The present workings have been confined to a limited area, in comparison to the properties as a whole; most of the developments are centered on the North Star group of five claims and are still in the prospective stage. The greatest depth attained is a nearly vertical shaft approximately 45 ft. in depth, following a fracture filled zone of brecciated quartz-monzonite 4 ft. in width, with low copper contents. (This shaft, for clarification in this report, is referred to as the Randall shaft.)

A similar condition was noted in an old, abandoned shaft about 200 ft. southerly from the Randall Shaft. This shaft, which is reported to be 340 ft. deep, and has a water level at 40 ft., was abandoned in the long past and no definite information is available, except the usual bizarre stories connected with old workings. Nevertheless, if the depth corresponds to the statements made, it should be unwatered at a later date, for what information it might lend to the geological data of the area.

Several open cuts of various dimensions have been opened, exposing the formations for study, particularly the faultings and subsidences and cross faultings and subsequent mineralization as the result of the cross faultings. Apart from the aforesaid surface exploratory work, no work has been performed of any consequence to evaluate the properties below the surface faulted zone.

SUMMARY:

The mineralization zone covers a considerable area and warrants a systematic evaluation of the holdings by one of the various geophysics methods applicable to this type of deposition. If the geophysics findings are favorable, the area should be core-drilled in a grid pattern, as a result of the geophysics map readings, to determine the value of the deeper mineralized zones beyond the zone of the surface faulting.

The surface mineralization so far uncovered is indicative of having originated from a depth below the surface fault zone.

Under the present and future market for copper, a high price is assured for a considerable period of years. The properties have sufficient merit to recommend their development. Another factor in favor of the properties is that they are located in an area adjacent to several commercial copper smelting plants, or if the ores result favorably for leaching, the chemicals essential for a leaching plant are produced and available in the State of Arizona.

Apropos to a leaching plant, a sufficient water supply would be required for this type of operation -- an economic problem that has not been determined at this writing.

GEOLOGIC REPORT

NORTH STAR MINE

Location

The North Star Mining property is located approximately 16 miles south of Florence, Arizona, and 56 miles north of Tucson, Arizona. The mine is located in Sections 7, 8, 9, Township 7 south, Range 10 East. The property is accessible by traveling on U. S. Highway 89 from Tucson to Florence, turning off between mile markers 117 and 118, thence turning west on a good country road for seven miles to the mine.

Physical Features

The North Star mine deposit is in the Sonora Desert section of the Basin and Range province and is in the Salt River Valley, which drains into the Mesa-Phoenix area, located 50 miles to the north. The mine is in a valley through. All streams in this area are intermittent. The mean annual Surface temperature of the area is about 71 degrees Fahrenheit. The rainfall is small, running about eight to eleven inches a year. The periods of greatest rainfall are in January and February and again in July and August, when sudden and violent local thunderstorms are common. The water table is at approximately 80 feet in depth, according to the incline shaft on the property.

Claim Description

There are 170 claims located in the North Star Mine Group, known As North Star #1 through 5 and others. These are on record in Florence, the county seat for Pinal County.

General Geology

The exact age of the rocks in the area has not been determined, but Presumably would date from Pre-Cambrian to recent. Except for the alluvial Deposits of Quaternary age, the rocks are all igneous, and the age of most of them can be identified only in a general way by correlation with rocks in the surrounding area. The mountain to the west of the immediate mining area is a Pre-Cambrian granite and schist. The fine grained granite located in the area of the 300' incline would be of Pre-Cambrian age or of the Mesozoic or early Tertiary age, correlating with the Ray and San Manuel District. The diabase material located in the northeast part of the map intrudes the monzonite and granite. The volcanic rocks and hyolite outcropping on the Three red hills where the main structure is open – cut, are of Tertiary age. Many younger dikes were noted on the property, striking in various directions but forming a general pattern from the northwest to the southwest directions.

The general structure indicates the strike to be from a northwest-southwest direction dipping from 30degrees to 60degrees to the southwest. This is noted on Hill No.1 of the main open-pit area and, can be traced to Hill No.2 and on the Hill No. 3, where the dip is considerably steeper. In the mid-workings of the property, the dip is a little flatter, about 30degrees west, the nearby 300degrees shaft is on a 45degree dip to the west.

Mineralogy and Ore Deposits

Chrysocolla and malachite are the predominant copper minerals in the oxidized zone of the copper-bearing rhyolite and the fine-grained granite. They are also present in the midworking area where residual sulphides are present. The three red hills have the prominent red color because of the leaching in the rhyolite and presence of oxidized iron. A supergene sulphide zone is below the oxidized ore, due to deposits of chalcocite and other secondary copper sulphides as replacement of primary pyrites and chalcopyrite, as can be seen in the deposit. For this reason, it will be necessary for a drilling program to determine the extent of a sulphide zone at depth. Chalcocite can either be hypogene or supergene, but in the majority of the cases in Arizona, it has been a supergene deposit as replacements of primary pyrite, chalcopyrite, and bornite. At the present time on Hill No. 1, a large open cut has been made, approximately 100,00 tons of leaching ore on the dump which will run from .50 to 1% copper. A sample of the dump ran .64% CU. This tonnage with the indicated reserve of the open cut, would justify a small leaching operation. However, the ore reserves could be enlarged by shallow drilling of the enriched zone.

Conclusions and Recommendations

Inferred Reserves. There is an inferred reserve of approximately 2-1/2 million Ton of oxide copper from the surface exposure. Mineralization is noted of 200 feet wide, 1500 feet long, and 100 feet in depth, at .80-1.00% copper. The gross value would be approximately \$9,000,000 per 100' depth of leaching material.

Due to the abundance of secondary copper minerals at the surface, secondary sulphides and primary copper minerals, this group has promise as a drilling property in containing a large ore body in depth. In the old incline, depth to 300', silver and copper of high-grade rank was found. This old incline is filled with water, but the dump indicates primary ore. Primary chalcopyrite and bornite were found in the open cut on Hill No. 1.

First – Geo-physical methods should be used in helping to outline potential favorable mineral areas.

Second – This primary ore could not have come from any great distance. The claims have a great amount of surface copper mineralization over most the claims. This itself would justify and warrant, first, a limited reconnaissance drilling program going to the depths of 100' for leaching to 1000' primary.

Third – Detailed drilling program.

Yours very truly,
Signed
H. Clyde Davis
Geologist

GEOLOGIC REPORT

NORTH STAR MINE

Location

The North Star Mining property is located approximately 16 miles south of Florence, Arizona, and 56 miles north of Tucson, Arizona. The mine is located in Sections 7, 8, 9, Township 7 South, Range 10 East. The property is accessible by traveling on U. S. Highway 89 from Tucson to Florence, turning off between mile markers 117 and 118, thence turning west on a good county road for seven miles to the mine.

Physical Features

The North Star mine deposit is in the Sonora Desert section of the Basin and Range province and is in the Salt River Valley, which drains into the Mesa-Phoenix area, located 50 miles to the north. The mine is in a valley trough. All streams in this area are intermittent. The mean annual surface temperature of the area is about 71° Fahrenheit. The rainfall is small, running about eight to eleven inches a year. The periods of greatest rainfall are in January and February and again in July and August, when sudden and violent local thunderstorms are common. The water table is at approximately 80 feet in depth, according to the incline shaft on the property.

Claim Description

There are 170 claims located in the North Star Mine Group, known as North Star #1 through 5 and others. These are on record in Florence, the county seat for Pinal County.

General Geology

The exact age of the rocks in the area has not been determined, but presumably would date from Pre-Cambrian to recent. Except for the alluvial deposits of Quaternary age, the rocks are all igneous, and the age of most of them can be identified only in a general way by correlation with rocks in the surrounding area. The mountain to the west of the immediate mining area is a Pre-Cambrian granite and schist. The fine-grained granite located in the area of the 300' incline would be of Pre-Cambrian age or of the Mesozoic or early Tertiary age, correlating with the Ray and San Manuel District. The diabase material located in the northeast part of the map intrudes the monzonite and granite. The volcanic rocks and hyolite outcropping on the three red hills where the main structure is open-cut, are of Tertiary age. Many younger dikes were noted on the property, striking in various directions but forming a general pattern from the northwest to the southeast directions.

The general structure indicates the strike to be from a northwest-southeast direction, dipping from 30° to 60° to the southwest. This is noted on Hill No. 1 of the main open-pit area, can be traced to Hill No. 2 and on the Hill No. 3, where the dip is considerably steeper. In the mid-workings of the property, the dip is a little flatter, about 30° west, the nearby 300' shaft is on a 45° dip to the west.

Mineralogy and Ore Deposits

Chrysacolla and malachite are the predominant copper minerals in the oxidized zone of the copper-bearing rhyolite and the fine-grained granite. They are also present in the midworking area where residual sulphides are present. The three red hills have the prominent red color because of the leaching in the rhyolite and presence of oxidized iron. A supergene sulphide zone is

below the oxidized ore, due to deposits of chalcocite and other secondary copper sulphides as replacement of primary pyrites and chalcopyrites, as can be seen in the deposit. For this reason, it will be necessary for a drilling program to determine the extent of a sulphide zone at depth. Chalcocite can either be hypogene or supergene, but in the majority of the cases in Arizona, it has been a supergene deposit as replacements of primary pyrite, chalcopyrite, and bornite. At the present mine on Hill No. 1, a large open cut has been made, approximately 100,000 tons of leaching ore on the dump which will run from .50 to 1% copper. A sample of the dump ran .64% CU. This tonnage, with the indicated reserves of the open cut, would justify a small leaching operation. However, the ore reserves could be enlarged by shallow drilling of this enriched zone.

Conclusions and Recommendations

Inferred Reserves. There is an inferred reserve of approximately 2-1/2 million Ton of oxide copper from the surface exposure. Mineralization is noted of 200 feet wide, 1500 feet long, and 100 feet in depth, at .80-1.00% copper. The gross value would be approximately \$9,000,000 per 100' feet depth of leaching material.

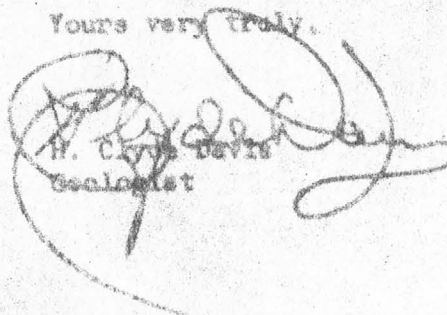

Due to the abundance of secondary copper minerals at the surface, secondary sulphides and primary copper minerals, this group has promise as a drilling property in containing a large ore body in depth. In the old incline, depth to 300', silver and copper of high-grade rank was found. This old incline is filled with water, but the dump indicates primary ore. Primary chalcopyrite and bornite were found in the open cut on Hill No. 1.

First -- Geo-physical methods should be used in helping to outline potential favorable mineral areas.

Second -- This primary ore could not have come from any great distance. The claims have a great amount of surface copper mineralization over most the claims. This itself would justify and warrant, first, a limited reconnaissance drilling program going to the depths of 100' for leaching to 1000' primary.

Third -- Detailed drilling program.

ROBERTA MINING AND PRODUCING COMPANY
PINAL COUNTY
FLORENCE, ARIZONA

SUMMARY OF 30 DAY OPERATING STATEMENT

Monthly Gross Profit - 302,400 lbs. @ 35c per pound copper, plant site, Florence, Arizona	\$105,840.00
Total Monthly Operating Cost (30 days)	52,899.04
One Month Operation Net Gross Income	52,950.96
Annual Net Gross Income	635,411.52
Before taxes and depreciation and financial Costs	

North Star

OPERATION COSTS BASED ON 302,400 LBS. CU.
PRODUCTION PER 30 DAY MONTH

A. Labor Cost

Condition based on 5 days per week,
8 hours per day, or 22 days per
month working hours.

Mining - Loading and Dozier:

8 employees @ \$4.00 per hour, per
worker - $8 \times 8 \times 30 \times \4.00

\$7,680.00

Hauling:

4 employees @ \$3.50 per hour,
per worker - $4 \times 8 \times 30 \times \3.50

3,360.00

Leaching: (24 hour runs)

4 employees @ \$3.50 per hour,
per worker - $4 \times 8 \times 30 \times \3.50

3,360.00

Maintenance and Repair:

1 employee @ \$3.30 per hour
 $1 \times 8 \times 22 \times \3.30

616.00

Total Monthly Labor Cost

\$15,016.00

B. Direct Operating Costs

Gas, Fuel and Oil:

1. Diesel - 200 gallons per day
@ 19¢ per gallon ($30 \times 200 \times 19¢$) 1,140.00
2. Gas - 100 gallons per day @
32.9¢ per gallon ($30 \times 100 \times 32.9¢$) 987.00
3. Butane - 500 gallons per day @
16¢ per gallon ($30 \times 500 \times 16¢$) 2,400.00
4. Oil - 55 gallons per 30 days 69.30
5. Maintenance, parts, tires and
repairs, etc. 100.00
6. Powder, fuse, caps, etc. 1,373.00
7. Acid (H_2SO_4), 60 tons per month
@ \$56.00 per ton 3,360.00
8. Scrap cans @ \$56.00 per ton,
225 tons per month 12,600.00

22,029.30

CURRENT PRODUCTION FIGURES

The report is based on 9 lb. Cu. per 1,000 gallons solution with 2 lbs. holdover in solution; dropping 7 lbs. Cu. per 1,000 gallons per minute flow through special (U.S. Patent Pending) copper precipitating, stainless steel, vats.

The copper ore assay shows better than one-half of one per cent (1/2 of 1%) Cu. It is mined and treated with sulphuric acid known as the Leaching Process, a standard procedure except for a new system that simplifies the operation for quicker recovery of the copper precipitates developed by O. L. Hill, and operating under the name of Roberts Mining and Producing Company.

Production Acid Flow Schedule:

1,000 gallons per minute produces 7 lbs. Cu. per minute.

1 hour produces 420 lbs. of Cu.

24 hours produces 10,080 lbs. Cu. (per day)

30 days operation produces a total of 302,400 lbs. of Cu.

At 35c per pound x 302,400 lbs. Cu.

Net Gross Income per month

\$105,840.00

ESTIMATED PRODUCTION COST PER EACH POUND
OF CU. PRODUCED ON BASIS OF 302,400 LBS.
OF CU. ON 30 DAY OPERATION

A. Labor	.0497
B. Direct Operating Cost	.0722
C. General Expenses	.0075
D. Management	.0372
E. Indirect Operating Cost	<u>.0080</u>
	.1746

The production cost is approximately 17 $\frac{1}{2}$ ¢ to 18¢ per lb. Cu.

C. General Expenses:

Legal and auditing services, insurance, payroll taxes, traveling expenses, office supplies, telephone and telegraph, auto expenses, miscellaneous, etc.

\$ 2,293.24

D. Management:

Executives, supervisor and administration

2,400.00

E. Indirect Operating Costs:

Freight and hauling \$800.00 per 40,000 lbs. \$5,500.00

Royalty payments @ 5% of gross

5,745.60

\$11,245.60

30 days, total operating cost to produce 302,400 lbs. of Cu.

\$52,989.14

DEPARTMENT OF MINERAL RESOURCES

STATE OF ARIZONA
FIELD ENGINEERS REPORT

Mine Northstar Mine Date 9-20-62
District Owlhead Dist., Pinal Co. Engineer Lewis A. Smith
Subject: Conference with Mike Guzman, at Superior, 9-20-62.

Mr. Guzman stated that Guzman and Schwartz were mining copper-silica ore at the Northstar and delivering it to Magma Copper Company's smelter. Mike said they were not making much on a carload a day. The ore runs about 85-87 percent silica with about 1.25 percent or less ~~silica~~ *in copper*. The ore is, with the exception of local chalcocite veinlets or blebs, oxidized to chrysocolla and some malachite.
