ACCESS STATEMENT

These digitized collections are accessible for purposes of education and research. We have indicated what we know about copyright and rights of privacy, publicity, or trademark. Due to the nature of archival collections, we are not always able to identify this information. We are eager to hear from any rights owners, so that we may obtain accurate information. Upon request, we will remove material from public view while we address a rights issue.

CONSTRAINTS STATEMENT

The Arizona Geological Survey does not claim to control all rights for all materials in its collection. These rights include, but are not limited to: copyright, privacy rights, and cultural protection rights. The User hereby assumes all responsibility for obtaining any rights to use the material in excess of "fair use."

The Survey makes no intellectual property claims to the products created by individual authors in the manuscript collections, except when the author deeded those rights to the Survey or when those authors were employed by the State of Arizona and created intellectual products as a function of their official duties. The Survey does maintain property rights to the physical and digital representations of the works.

QUALITY STATEMENT

The Arizona Geological Survey is not responsible for the accuracy of the records, information, or opinions that may be contained in the files. The Survey collects, catalogs, and archives data on mineral properties regardless of its views of the veracity or accuracy of those data.

HEINRICHS GEOEXPLORATION COMPANY

806 WEST GRANT ROAD, TUCSON, ARIZONA, 85703. P.O. BOX 5671. PHONE: (AREA CODE 602) 623-0578

November 30, 1966

**Mr. Woodrow Mullin
Box 455
Turkey, Texas**

Dear Mr. Mullin:

As per your request in our discussions in our office between John Langa and E. Grover Heinrichs and Mr. Molloy on November 16, 1966, the following proposals are suggested to best evaluate the water potential on your property on the Pierce Area, Arizona.

From the well data given on wells 1 through 4 drilled in Section 15, T17S, R25E, the apparent subsurface structure is a generally north trending trough, as shown on the enclosed cross section. However, the strike of this trough may be concordant with major northwest trending structure in the area. The water table dips to the north indicating subsurface flow in this direction. The maximum production out of well #1 shows the relationship between increased depth of alluvium and corresponding thickness of water zone and increased rate of production.

Improved water production is related to locating increased depth to bedrock and corresponding head.

The following methods of exploration are recommended and presented for consideration. Proposed lines are shown on the enclosed plan view of Section 15.

1. Gravity is the first choice and would give the most accurate picture of the subsurface bedrock topography. A minimum of 9 line miles, at \$150.00/mile with a \$1,000.00 minimum fee, is recommended if this method is used.
2. Resistivity is second choice, and should give a good indication of bedrock topography and possible depth to

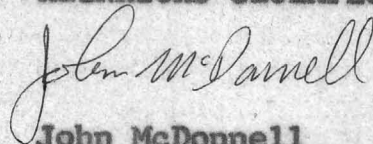

water table. Three line miles, at \$500.00/mile is recommended if this method is used.

3. Magnetics is third and would give a general indication of the shape of the trough. This method will not give as good information as gravity or probably resistivity, but it may show the location of thickest alluvium. Nine miles at \$50.00/mile is recommended if this method is used.

For increased effectiveness, a combination of two or all three of the above methods should be considered.

Respectfully submitted,

HEINRICHS GEOEXPLORATION COMPANY

John McDonnell
Geologist

APPROVED:

Bouguer Gravity Contour Plan	

INTRODUCTION

As a result of a letter to Mr. Mullin dated November 30, 1966 from Heinrichs Geoexploration Company which outlined methods of exploration to evaluate water potential in Section 15, T17S, R25E, in Cochise County, near Pearce, Arizona, a telephone conversation was held December 6, 1966 between Mr. Woodrow Mullin and John W. Langs of Geoex. It was decided that Geoex would conduct a preliminary semi reconnaissance-semi detailed gravity survey consisting of five lines totaling seven line miles. Mr. Roy Molloy of Cochise, Arizona would conduct the level survey and locate stations as directed by Geoex.

Other Geoex personnel involved were R. E. Palmer, field party chief, and M. J. Fraker, field assistant, interpretation by Chris S. Ludwig, senior geophysicist, and report by John McDonnell, geologist.

A gravity contour and interpretation plan at a scale of one inch to 500 feet with a contour interval of 0.25 milligals is included in the report.

PROCEDURE

The topographic level survey conducted by Roy Molloy consisted of 124 stations with a 300 foot station spacing on five E-W lines. Of these lines the southern-most was three miles in length, and the other four were one mile in length. Lines were located 1/4 mile apart.

A Texas Instruments gravity meter with a scale constant of 0.09640 milligals per scale division was used. Maximum observed instrumental drift was 0.67 milligals and all drifts were loop corrected. The combined Bouguer and free air correction factor was 0.06854 milligals per foot with an inferred alluvial density of 2.0 g/cc. The latitude correction factor was 1.175 milligals per mile.

INTERPRETATION, CONCLUSIONS, AND RECOMMENDATIONS

Gravity values in the area increase to the east from the west boundary of Section 15 showing a decrease in depth to bedrock to the east. The least gravity value (and therefore, approximate location of probable thickest alluvium) in the entire survey is on the south boundary of Section 16 at Station 113. A channel trending NW across Section 15 from the SW quarter is indicated.

If Section 16 is available, the most favorable location according to the entire survey, is in the vicinity of Station 113, with an inferred depth of about 740 feet to bedrock. The depth increase over well #1 is about 110 feet giving a probable head of approximately 410 feet. This location is marked on the map as proposed well site #1.

The most favorable water well location in Section 15, from the standpoint of the gravity results is in the SW corner of the section. Inferred depth to bedrock here is about 690 feet with an increase of about 60 feet over depth to bedrock in your well #1. Probable head should be around 330 feet. This location is marked on the map as proposed well site #2. Another low point is noted in the NW corner of Section 15. Inferred depth to bedrock there is approximately 550 feet. Assuming relatively uniform character of the alluvial sediments, a well in this location would probably give less production than well #1 because of less head. This location is marked on the map as proposed well site 3.

Should Section 16 be available, two additional line miles of gravity survey are recommended to define the suggested trough-like feature between Stations 112 and 114. The two lines should be run E-W with 300 foot spacings between stations. One line should be run 1/2 mile north of the south boundary of the section and the other across the north boundary of the section.

Because of the proximity of existing well #1 to this proposed well site, cost of drilling versus increased production should be considered. A 50% increase over well #1 would give

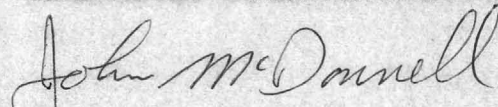

about 1700 gallons per minute. This increase is calculated on the basis of increased depth alone with no consideration of lateral feed from the deeper area to the west. Dual production from the proposed well and well #1 versus shutdown of well #1 should be considered. Drawdown from the proposed well could decrease production from well #1 to make its shut-down necessary.

From the data presently available, 2,000 gallons per minute does not appear likely from a single well in Section 15. A combined production from the proposed well and other wells on the section could give equivalent production.

The NW-SE trending buried bedrock stream channel through Section 15 could be water bearing, but with a limited head, and is not recommended for testing at this time.
